YANG Schema Mount
draft-ietf-netmod-schema-mount-06

Abstract

   This document defines a mechanism to combine YANG modules into the
   schema defined in other YANG modules.

Status of This Memo

   This Internet-Draft is submitted in full conformance with the
   provisions of BCP 78 and BCP 79.

   Internet-Drafts are working documents of the Internet Engineering
   Task Force (IETF). Note that other groups may also distribute
   working documents as Internet-Drafts. The list of current Internet-
   Drafts is at http://datatracker.ietf.org/drafts/current/.

   Internet-Drafts are draft documents valid for a maximum of six months
   and may be updated, replaced, or obsoleted by other documents at any
   time. It is inappropriate to use Internet-Drafts as reference
   material or to cite them other than as "work in progress."

   This Internet-Draft will expire on January 6, 2018.

1. Introduction

   Modularity and extensibility were among the leading design principles
   of the YANG data modeling language. As a result, the same YANG
   module can be combined with various sets of other modules and thus
   form a data model that is tailored to meet the requirements of a
   specific use case. Server implementors are only required to specify
   all YANG modules comprising the data model (together with their
   revisions and other optional choices) in the YANG library data
   ([RFC7895], and Section 5.6.4 of [RFC7950]) implemented by the
   server. Such YANG modules appear in the data model "side by side",
   i.e., top-level data nodes of each module - if there are any - are
   also top-level nodes of the overall data model.

   Furthermore, YANG has two mechanisms for contributing a schema
   hierarchy defined elsewhere to the contents of an internal node of
   the schema tree; these mechanisms are realized through the following
   YANG statements:

o The "uses" statement explicitly incorporates the contents of a
   grouping defined in the same or another module. See Section 4.2.6
   of [RFC7950] for more details.

o The "augment" statement explicitly adds contents to a target node
   defined in the same or another module. See Section 4.2.8 of
   [RFC7950] for more details.

With both mechanisms, the source or target YANG module explicitly
defines the exact location in the schema tree where the new nodes are
placed.

In some cases these mechanisms are not sufficient; it is often
necessary that an existing module (or a set of modules) is added to
the data model starting at a non-root location. For example, YANG
modules such as "ietf-interfaces" [RFC7223] are often defined so as
to be used in a data model of a physical device. Now suppose we want
to model a device that supports multiple logical devices
[I-D.ietf-rtgwg-lne-model], each of which has its own instantiation
of "ietf-interfaces", and possibly other modules, but, at the same
time, we want to be able to manage all these logical devices from the
master device. Hence, we would like to have a schema like this:

```
  +--rw interfaces
  |  +--rw interface* [name]
  |      ...
  +--rw logical-device* [name]
     +--rw name
     |   ...
     +--rw interfaces
       +--rw interface* [name]
          ...
```

With the "uses" approach, the complete schema tree of
"ietf-interfaces" would have to be wrapped in a grouping, and then
this grouping would have to be used at the top level (for the master
device) and then also in the "logical-device" list (for the logical
devices). This approach has several disadvantages:

o It is not scalable because every time there is a new YANG module
   that needs to be added to the logical device model, we have to
   update the model for logical devices with another "uses" statement
   pulling in contents of the new module.

o Absolute references to nodes defined inside a grouping may break
   if the grouping is used in different locations.

   o Nodes defined inside a grouping belong to the namespace of the
      module where it is used, which makes references to such nodes from
      other modules difficult or even impossible.

   o It would be difficult for vendors to add proprietary modules when
      the "uses" statements are defined in a standard module.

   With the "augment" approach, "ietf-interfaces" would have to augment
   the "logical-device" list with all its nodes, and at the same time
   define all its nodes at the top level. The same hierarchy of nodes
   would thus have to be defined twice, which is clearly not scalable
   either.

   This document introduces a new generic mechanism, denoted as schema
   mount, that allows for mounting one data model consisting of any
   number of YANG modules at a specified location of another (parent)
   schema. Unlike the "uses" and "augment" approaches discussed above,
   the mounted modules needn't be specially prepared for mounting and,
   consequently, existing modules such as "ietf-interfaces" can be
   mounted without any modifications.

   The basic idea of schema mount is to label a data node in the parent
   schema as the mount point, and then define a complete data model to
   be attached to the mount point so that the labeled data node
   effectively becomes the root node of the mounted data model.

   In principle, the mounted schema can be specified at three different
   phases of the data model life cycle:

   1. Design-time: the mounted schema is defined along with the mount
       point in the parent YANG module. In this case, the mounted
       schema has to be the same for every implementation of the parent
       module.

   2. Implementation-time: the mounted schema is defined by a server
       implementor and is as stable as YANG library information, i.e.,
       it may change after an upgrade of server software but not after
       rebooting the server. Also, a client can learn the entire schema
       together with YANG library data.

   3. Run-time: the mounted schema is defined by instance data that is
       part of the mounted data model. If there are multiple instances
       of the same mount point (e.g., in multiple entries of a list),
       the mounted data model may be different for each instance.

   The schema mount mechanism defined in this document provides support
   only for the latter two cases. Design-time mounts are outside the

scope of this document, and could be possibly dealt with in a future
revision of the YANG data modeling language.

Schema mount applies to the data model, and specifically does not
assume anything about the source of instance data for the mounted
schemas. It may be implemented using the same instrumentation as the
rest of the system, or it may be implemented by querying some other
system. Future specifications may define mechanisms to control or
monitor the implementation of specific mount points.

This document allows mounting of complete data models only. Other
specifications may extend this model by defining additional
mechanisms such as mounting sub-hierarchies of a module.

2. Terminology and Notation

The keywords "MUST", "MUST NOT", "REQUIRED", "SHALL", "SHALL NOT",
"SHOULD", "SHOULD NOT", "RECOMMENDED", "NOT RECOMMENDED", "MAY", and
"OPTIONAL" in this document are to be interpreted as described in BCP
14, [RFC2119].

The following terms are defined in [RFC6241] and are not redefined
here:

o client

o notification

o server

The following terms are defined in [RFC7950] and are not redefined
here:

o action

o configuration data

o container

o list

o operation

The following terms are defined in [RFC7223] and are not redefined
here:

o system-controlled interface

Tree diagrams used in this document follow the notation defined in
[I-D.ietf-netmod-yang-tree-diagrams].

2.1. Glossary of New Terms

o inline schema: a mounted schema whose definition is provided as
   part of the mounted data, using YANG library [RFC7895].

o mount point: container or list node whose definition contains the
   "mount-point" extension statement. The argument of the
   "mount-point" statement defines the name of the mount point.

o parent schema (of a particular mounted schema): the schema that
   contains the mount point for the mounted schema.

o top-level schema: a schema according to [RFC7950] in which schema
   trees of each module (except augments) start at the root node.

2.2. Namespace Prefixes

In this document, names of data nodes, YANG extensions, actions and
other data model objects are often used without a prefix, as long as
it is clear from the context in which YANG module each name is
defined. Otherwise, names are prefixed using the standard prefix
associated with the corresponding YANG module, as shown in Table 1.

```
+---------+------------------------+-----------+
| Prefix  | YANG module            | Reference |
+---------+------------------------+-----------+
| yangmnt | ietf-yang-schema-mount | Section 8 |
| inet    | ietf-inet-types        | [RFC6991] |
| yang    | ietf-yang-types        | [RFC6991] |
| yanglib | ietf-yang-library      | [RFC7895] |
+---------+------------------------+-----------+
```

Table 1: Namespace Prefixes

3. Schema Mount

The schema mount mechanism defined in this document provides a new
extensibility mechanism for use with YANG 1.1. In contrast to the
existing mechanisms described in Section 1, schema mount defines the
relationship between the source and target YANG modules outside these
modules. The procedure consists of two separate steps that are
described in the following subsections.

3.1. Mount Point Definition

A "container" or "list" node becomes a mount point if the
"mount-point" extension (defined in the "ietf-yang-schema-mount"
module) is used in its definition. This extension can appear only as
a substatement of "container" and "list" statements.

The argument of the "mount-point" extension is a YANG identifier that
defines the name of the mount point. A module MAY contain multiple
"mount-point" statements having the same argument.

It is therefore up to the designer of the parent schema to decide
about the placement of mount points. A mount point can also be made
conditional by placing "if-feature" and/or "when" as substatements of
the "container" or "list" statement that represents the mount point.

The "mount-point" statement MUST NOT be used in a YANG version 1
module. Note, however, that modules written in any YANG version,
including version 1, can be mounted under a mount point.

3.2. Specification of the Mounted Schema

Mounted schemas for all mount points in the parent schema are
determined from state data in the "yangmnt:schema-mounts" container.
Data in this container is intended to be as stable as data in the
top-level YANG library [RFC7895]. In particular, it SHOULD NOT
change during the same management session.

Generally, the modules that are mounted under a mount point have no
relation to the modules in the parent schema; specifically, if a
module is mounted it may or may not be present in the parent schema
and, if present, its data will generally have no relationship to the
data of the parent. Exceptions are possible and such needs to be
defined in the model defining the exception, e.g., the interface
module in [I-D.ietf-rtgwg-lne-model].

The "schema-mounts" container has the "mount-point" list as one of
its children. Every entry of this list refers through its key to a
mount point and specifies the mounted schema.

If a mount point is defined in the parent schema but does not have an
entry in the "mount-point" list, then the mounted schema is void,
i.e., instances of that mount point MUST NOT contain any data above
those that are defined in the parent schema.

If multiple mount points with the same name are defined in the same
module - either directly or because the mount point is defined in a
grouping and the grouping is used multiple times - then the

corresponding "mount-point" entry applies equally to all such mount
points.

The "config" property of mounted schema nodes is overridden and all
nodes in the mounted schema are read-only ("config false") if at
least one of the following conditions is satisfied for a mount point:

o   the mount point is itself defined as "config false"

o   the "config" leaf in the corresponding entry of the "mount-point"
    list is set to "false".

An entry of the "mount-point" list can specify the mounted schema in
two different ways:

1. by stating that the schema is available inline, i.e., in run-time
    instance data; or

2. by referring to one or more entries of the "schema" list in the
    same instance of "schema-mounts".

In case 1, the mounted schema is determined at run time: every
instance of the mount point that exists in the parent tree MUST
contain a copy of YANG library data [RFC7895] that defines the
mounted schema exactly as for a top-level data model. A client is
expected to retrieve this data from the instance tree, possibly after
creating the mount point. Instances of the same mount point MAY use
different mounted schemas.

In case 2, the mounted schema is defined by the combination of all
"schema" entries referred to in the "use-schema" list. In this case,
the mounted schema is specified as implementation-time data that can
be retrieved together with YANG library data for the parent schema,
i.e., even before any instances of the mount point exist. However,
the mounted schema has to be the same for all instances of the mount
point. Note, that in this case a mount point may include a mounted
YANG library module and the data contained in the mounted module MUST
exactly match the data contained in the "schema" entries associated
with the mount point.

Each entry of the "schema" list contains:

o   a list in the YANG library format specifying all YANG modules (and
    revisions etc.) that are implemented or imported in the mounted
    schema. Note that this includes modules that solely augment other
    listed modules;

o (optionally) a new "mount-point" list that applies to mount points
   defined within the mounted schema.

3.3. Multiple Levels of Schema Mount

YANG modules in a mounted schema MAY again contain mount points under
which subschemas can be mounted. Consequently, it is possible to
construct data models with an arbitrary number of schema levels. A
subschema for a mount point contained in a mounted module can be
specified in one of the following ways:

o by implementing "ietf-yang-library" and "ietf-yang-schema-mount"
   modules in the mounted schema, and specifying the subschemas
   exactly as it is done in the top-level schema

o by using the "mount-point" list inside the corresponding "schema"
   entry.

The former method is applicable to both "inline" and "use-schema"
cases whereas the latter requires the "use-schema" case. On the
other hand, the latter method allows for a compact representation of
a multi-level schema the does not rely on the presence of any
instance data.

4. Referring to Data Nodes in the Parent Schema

A fundamental design principle of schema mount is that the mounted
data model works exactly as a top-level data model, i.e., it is
confined to the "mount jail". This means that all paths in the
mounted data model (in leafrefs, instance-identifiers, XPath
expressions, and target nodes of augments) are interpreted with the
mount point as the root node. YANG modules of the mounted schema as
well as corresponding instance data thus cannot refer to schema nodes
or instance data outside the mount jail.

However, this restriction is sometimes too severe. A typical example
is network instances (NI) [I-D.ietf-rtgwg-ni-model], where each NI
has its own routing engine but the list of interfaces is global and
shared by all NIs. If we want to model this organization with the NI
schema mounted using schema mount, the overall schema tree would look
schematically as follows:

```
+--rw interfaces
|  +--rw interface* [name]
|     ...
+--rw network-instances
   +--rw network-instance* [name]
      +--rw name
      +--rw root
         +--rw routing
            ...
```

Here, the "root" node is the mount point for the NI schema. Routing
configuration inside an NI often needs to refer to interfaces (at
least those that are assigned to the NI), which is impossible unless
such a reference can point to a node in the parent schema (interface
name).

Therefore, schema mount also allows for such references. For every
schema mounted using the "use-schema" method, it is possible to
specify a leaf-list named "parent-reference" that contains zero or
more XPath 1.0 expressions. Each expression is evaluated with the
root of the parent data tree as the context node and the result MUST
be a nodeset (see the description of the "parent-reference" node for
a complete definition of the evaluation context). For the purposes
of evaluating XPath expressions within the mounted data tree, the
union of all such nodesets is added to the accessible data tree.

It is worth emphasizing that

o The nodes specified in "parent-reference" leaf-list are available
   in the mounted schema only for XPath evaluations. In particular,
   they cannot be accessed there via network management protocols
   such as NETCONF [RFC6241] or RESTCONF [RFC8040].

o The mechanism of referencing nodes in the parent schema is not
   available for schemas mounted using the "inline" method.

5. RPC operations and Notifications

If a mounted YANG module defines an RPC operation, clients can invoke
this operation by representing it as an action defined for the
corresponding mount point, see Section 7.15 of ^RFC7950. An example
of this is given in Appendix A.4.

Similarly, if the server emits a notification defined at the top
level of any mounted module, it MUST be represented as if the
notification was connected to the mount point, see Section 7.16 of
[RFC7950].

Note, inline actions and notifications will not work when they are
contained within a list node without a "key" statement (see section
7.15 and 7.16 of [RFC7950]). Therefore, to be useful, mount points
which contain modules with RPCs, actions, and notifications SHOULD
NOT have any ancestor node that is a list node without a "key"
statement. This requirement applies to the definition of modules
using the "mount-point" extension statement.

6. Implementation Notes

Network management of devices that use a data model with schema mount
can be implemented in different ways. However, the following
implementations options are envisioned as typical:

o   shared management: instance data of both parent and mounted
    schemas are accessible within the same management session.

o   split management: one (master) management session has access to
    instance data of both parent and mounted schemas but, in addition,
    an extra session exists for every instance of the mount point,
    having access only to the mounted data tree.

7. Data Model

This document defines the YANG 1.1 module [RFC7950]
"ietf-yang-schema-mount", which has the following structure:

```
module: ietf-yang-schema-mount
    +--ro schema-mounts
       +--ro namespace* [prefix]
       |  +--ro prefix    yang:yang-identifier
       |  +--ro uri?       inet:uri
       +--ro mount-point* [module name]
       |  +--ro module         yang:yang-identifier
       |  +--ro name           yang:yang-identifier
       |  +--ro config?        boolean
       |  +--ro (schema-ref)?
       |     +--:(inline)
       |     |  +--ro inline?        empty
       |     +--:(use-schema)
       |        +--ro use-schema* [name]
       |           +--ro name
       |           |        -> /schema-mounts/schema/name
       |           +--ro parent-reference*    yang:xpath1.0
       +--ro schema* [name]
          +--ro name               string
          +--ro module* [name revision]
          |  +--ro name                 yang:yang-identifier
          |  +--ro revision             union
          |  +--ro schema?              inet:uri
          |  +--ro namespace            inet:uri
          |  +--ro feature*             yang:yang-identifier
          |  +--ro deviation* [name revision]
          |  |  +--ro name         yang:yang-identifier
          |  |  +--ro revision     union
          |  +--ro conformance-type     enumeration
          |  +--ro submodule* [name revision]
          |     +--ro name         yang:yang-identifier
          |     +--ro revision     union
          |     +--ro schema?      inet:uri
          +--ro mount-point* [module name]
             +--ro module         yang:yang-identifier
             +--ro name           yang:yang-identifier
             +--ro config?        boolean
             +--ro (schema-ref)?
                +--:(inline)
                |  +--ro inline?        empty
                +--:(use-schema)
                   +--ro use-schema* [name]
                      +--ro name
                      |        -> /schema-mounts/schema/name
                      +--ro parent-reference*    yang:xpath1.0
```

8. Schema Mount YANG Module

   This module references [RFC6991] and [RFC7895].

extension mount-point {
  argument name;
  description
    "The argument 'name' is a YANG identifier, i.e., it is of the
     type 'yang:yang-identifier'.

     The 'mount-point' statement MUST NOT be used in a YANG
     version 1 module, neither explicitly nor via a 'uses'
     statement.

     The 'mount-point' statement MAY be present as a substatement
     of 'container' and 'list', and MUST NOT be present elsewhere.

     If a mount point is defined in a grouping, its name is bound
     to the module where the grouping is used.

     A mount point defines a place in the node hierarchy where
     other data models may be attached. A server that implements a

```
      module with a mount point populates the
      /schema-mounts/mount-point list with detailed information on
      which data models are mounted at each mount point.";
  }

              description
                "This leaf indicates that the server has mounted
                 'ietf-yang-library' and 'ietf-schema-mount' at the mount
                 point, and their instantiation (i.e., state data
                 containers 'yanglib:modules-state' and 'schema-mounts')
                 provides the information about the mounted schema.";
            }
            list use-schema {
              key "name";
              description
                "Each entry of this list contains a reference to a schema
                 defined in the /schema-mounts/schema list.";
              leaf name {
                type leafref {
                  path "/schema-mounts/schema/name";
                }
                description
                  "Name of the referenced schema.";
              }
              leaf-list parent-reference {
                type yang:xpath1.0;
                description
                  "Entries of this leaf-list are XPath 1.0 expressions
                   that are evaluated in the following context:

                    - The context node is the root node of the parent data
                      tree.

                    - The accessible tree is the parent data tree
                      *without* any nodes defined in modules that are
                      mounted inside the parent schema.

                    - The context position and context size are both equal
                      to 1.

                    - The set of variable bindings is empty.

                    - The function library is the core function library
                      defined in [XPath] and the functions defined in
                      Section 10 of [RFC7950].

                    - The set of namespace declarations is defined by the
```

```
                    'namespace' list under 'schema-mounts'.

                    Each XPath expression MUST evaluate to a nodeset
                    (possibly empty). For the purposes of evaluating XPath
                    expressions whose context nodes are defined in the
                    mounted schema, the union of all these nodesets
                    together with ancestor nodes are added to the
                    accessible data tree.";
              }
            }
          }
        }
      }

      /*
       * State data nodes
       */

      container schema-mounts {
        config false;
        description
          "Contains information about the structure of the overall
           mounted data model implemented in the server.";
        list namespace {
          key "prefix";
          description
            "This list provides a mapping of namespace prefixes that are
             used in XPath expressions of 'parent-reference' leafs to the
             corresponding namespace URI references.";
          leaf prefix {
            type yang:yang-identifier;

9. IANA Considerations

   This document registers a URI in the IETF XML registry [RFC3688].
   Following the format in RFC 3688, the following registration is
   requested to be made.

      URI: urn:ietf:params:xml:ns:yang:ietf-yang-schema-mount

      Registrant Contact: The IESG.

      XML: N/A, the requested URI is an XML namespace.

   This document registers a YANG module in the YANG Module Names
   registry [RFC6020].

```
  name:        ietf-yang-schema-mount
  namespace:   urn:ietf:params:xml:ns:yang:ietf-yang-schema-mount
  prefix:      yangmnt
  reference:   RFC XXXX
```

10. Security Considerations

   TBD

11. Contributors

   The idea of having some way to combine schemas from different YANG
   modules into one has been proposed independently by several groups of
   people: Alexander Clemm, Jan Medved, and Eric Voit
   ([I-D.clemm-netmod-mount]); and Lou Berger and Christian Hopps:

   o Lou Berger, LabN Consulting, L.L.C., <lberger@labn.net>

   o Alexander Clemm, Huawei, <alexander.clemm@huawei.com>

   o Christian Hopps, Deutsche Telekom, <chopps@chopps.org>

   o Jan Medved, Cisco, <jmedved@cisco.com>

   o Eric Voit, Cisco, <evoit@cisco.com>

Appendix A. Example: Device Model with LNEs and NIs

This non-normative example demonstrates an implementation of the
device model as specified in Section 2 of
[I-D.ietf-rtgwg-device-model], using both logical network elements
(LNE) and network instances (NI).

A.1. Physical Device

   The data model for the physical device may be described by this YANG
   library content:

```
"ietf-yang-library:modules-state": {
  "module-set-id": "14e2ab5dc325f6d86f743e8d3ade233f1a61a899",
  "module": [
    {
      "name": "iana-if-type",
      "revision": "2014-05-08",
      "namespace": "urn:ietf:params:xml:ns:yang:iana-if-type",
      "conformance-type": "implement"
    },
    {
      "name": "ietf-inet-types",
      "revision": "2013-07-15",
      "namespace": "urn:ietf:params:xml:ns:yang:ietf-inet-types",
      "conformance-type": "import"
    },
    {
      "name": "ietf-interfaces",
      "revision": "2014-05-08",
      "feature": [
        "arbitrary-names",
        "pre-provisioning"
      ],
      "namespace": "urn:ietf:params:xml:ns:yang:ietf-interfaces",
      "conformance-type": "implement"
    },
    {
      "name": "ietf-ip",
      "revision": "2014-06-16",
      "namespace": "urn:ietf:params:xml:ns:yang:ietf-ip",
      "conformance-type": "implement"
    },
    {
      "name": "ietf-logical-network-element",
      "revision": "2016-10-21",
      "feature": [
        "bind-lne-name"
      ],
      "namespace":
        "urn:ietf:params:xml:ns:yang:ietf-logical-network-element",
      "conformance-type": "implement"
    },
    {
      "name": "ietf-yang-library",
```

```
          "revision": "2016-06-21",
          "namespace": "urn:ietf:params:xml:ns:yang:ietf-yang-library",
          "conformance-type": "implement"
        },
        {
          "name": "ietf-yang-schema-mount",
          "revision": "2017-05-16",
          "namespace":
            "urn:ietf:params:xml:ns:yang:ietf-yang-schema-mount",
          "conformance-type": "implement"
        },
        {
          "name": "ietf-yang-types",
          "revision": "2013-07-15",
          "namespace": "urn:ietf:params:xml:ns:yang:ietf-yang-types",
          "conformance-type": "import"
        }
      ]
    }
```

A.2. Logical Network Elements

Each LNE can have a specific data model that is determined at run
time, so it is appropriate to mount it using the "inline" method,
hence the following "schema-mounts" data:

```
"ietf-yang-schema-mount:schema-mounts": {
  "mount-point": [
    {
      "module": "ietf-logical-network-element",
      "name": "root",
      "inline": [null]
    }
  ]
}
```

An administrator of the host device has to configure an entry for
each LNE instance, for example,

```
      {
        "ietf-interfaces:interfaces": {
          "interface": [
            {
              "name": "eth0",
              "type": "iana-if-type:ethernetCsmacd",
              "enabled": true,
              "ietf-logical-network-element:bind-lne-name": "eth0"
            }
          ]
        },
        "ietf-logical-network-element:logical-network-elements": {
          "logical-network-element": [
            {
              "name": "lne-1",
              "managed": true,
              "description": "LNE with NIs",
              "root": {
                 ...
              }
            },
            ...
          ]
        }
      }
```

   and then also place necessary state data as the contents of the
   "root" instance, which should include at least

   o YANG library data specifying the LNE's data model, for example:

```
   "ietf-yang-library:modules-state": {
     "module-set-id": "9358e11874068c8be06562089e94a89e0a392019",
     "module": [
       {
         "name": "iana-if-type",
         "revision": "2014-05-08",
         "namespace": "urn:ietf:params:xml:ns:yang:iana-if-type",
         "conformance-type": "implement"
       },
       {
         "name": "ietf-inet-types",
         "revision": "2013-07-15",
         "namespace": "urn:ietf:params:xml:ns:yang:ietf-inet-types",
         "conformance-type": "import"
       },
       {
         "name": "ietf-interfaces",
```

```
          "revision": "2014-05-08",
          "feature": [
            "arbitrary-names",
            "pre-provisioning"
          ],
          "namespace": "urn:ietf:params:xml:ns:yang:ietf-interfaces",
          "conformance-type": "implement"
        },
        {
          "name": "ietf-ip",
          "revision": "2014-06-16",
          "feature": [
            "ipv6-privacy-autoconf"
          ],
          "namespace": "urn:ietf:params:xml:ns:yang:ietf-ip",
          "conformance-type": "implement"
        },
        {
          "name": "ietf-network-instance",
          "revision": "2016-10-27",
          "feature": [
            "bind-network-instance-name"
          ],
          "namespace":
            "urn:ietf:params:xml:ns:yang:ietf-network-instance",
          "conformance-type": "implement"
        },
        {
          "name": "ietf-yang-library",
          "revision": "2016-06-21",
          "namespace": "urn:ietf:params:xml:ns:yang:ietf-yang-library",
          "conformance-type": "implement"
        },
        {
          "name": "ietf-yang-schema-mount",
          "revision": "2017-05-16",
          "namespace":
            "urn:ietf:params:xml:ns:yang:ietf-yang-schema-mount",
          "conformance-type": "implement"
        },
        {
          "name": "ietf-yang-types",
          "revision": "2013-07-15",
          "namespace": "urn:ietf:params:xml:ns:yang:ietf-yang-types",
          "conformance-type": "import"
        }
      ]
    }
```

   o state data for interfaces assigned to the LNE instance (that
      effectively become system-controlled interfaces for the LNE), for
      example:

   "ietf-interfaces:interfaces-state": {
     "interface": [
       {
         "name": "eth0",
         "type": "iana-if-type:ethernetCsmacd",
         "oper-status": "up",
         "statistics": {
           "discontinuity-time": "2016-12-16T17:11:27+02:00"
         },
         "ietf-ip:ipv6": {
           "address": [
             {
               "ip": "fe80::42a8:f0ff:fea8:24fe",
               "origin": "link-layer",
               "prefix-length": 64
             }
           ]
         }
       },
       ...
     ]
   }

A.3. Network Instances

   Assuming that network instances share the same data model, it can be
   mounted using the "use-schema" method as follows:

   "ietf-yang-schema-mount:schema-mounts": {
     "namespace": [
       {
           "prefix": "if",
           "uri": "urn:ietf:params:xml:ns:yang:ietf-interfaces"
       }
     ],
     "mount-point": [
       {
         "module": "ietf-network-instance",
         "name": "root",
         "use-schema": [
           {
             "name": "ni-schema",
             "parent-reference": ["/if:interfaces"]
           }

```
          ]
        }
      ],
      "schema": [
        {
          "name": "ni-schema",
          "module": [
            {
              "name": "ietf-ipv4-unicast-routing",
              "revision": "2016-11-04",
              "namespace":
               "urn:ietf:params:xml:ns:yang:ietf-ipv4-unicast-routing",
              "conformance-type": "implement"
            },
            {
              "name": "ietf-ipv6-unicast-routing",
              "revision": "2016-11-04",
              "namespace":
               "urn:ietf:params:xml:ns:yang:ietf-ipv6-unicast-routing",
              "conformance-type": "implement"
            },
            {
              "name": "ietf-routing",
              "revision": "2016-11-04",
              "feature": [
                "multiple-ribs",
                "router-id"
              ],
              "namespace": "urn:ietf:params:xml:ns:yang:ietf-routing",
              "conformance-type": "implement"
            }
          ]
        }
      ]
    }
```

   Note also that the "ietf-interfaces" module appears in the
   "parent-reference" leaf-list for the mounted NI schema. This means
   that references to LNE interfaces, such as "outgoing-interface" in
   static routes, are valid despite the fact that "ietf-interfaces"
   isn't part of the NI schema.

A.4. Invoking an RPC Operation

   Assume that the mounted NI data model also implements the "ietf-isis"
   module [I-D.ietf-isis-yang-isis-cfg]. An RPC operation defined in
   this module, such as "clear-adjacency", can be invoked by a client
   session of a LNE's RESTCONF server as an action tied to a the mount

point of a particular network instance using a request URI like this
(all on one line):

```
POST /restconf/data/ietf-network-instance:network-instances/
    network-instance=rtrA/root/ietf-isis:clear-adjacency HTTP/1.1
```
